Animal Form And Function Activity

Animal Form and Function Review Animals are complex systems of cells working in a coordinated fashion to monitor changing external conditions while maintaining a constant internal environment. To accomplish these tasks, animal cells are organized into systems that are specialized for particular functions.

Concept 40.3 Animals use the chemical energy in food to sustain form and function. All organisms require chemical energy for growth, physiological processes, maintenance and repair, regulation, and reproduction. Plants use light energy to build energy-rich organic molecules from water and CO₂, and then they use those organic molecules for fuel.

Animal body plans follow set patterns related to symmetry. They are asymmetrical, radial, or bilateral in form as illustrated in Figure 1. Asymmetrical animals are animals with no pattern or symmetry; an example of an asymmetrical animal is a sponge. Radial symmetry, as illustrated in Figure 1, describes when an animal has an up-and-down orientation: any plane cut along its longitudinal axis ...

Animal Form and Function. Animals vary in form and function. From a sponge to a worm to a goat, an organism has a distinct body plan that limits its size and shape. The term body plan is the "blueprint" encompassing aspects such as symmetry, segmentation, and limb disposition.

These animals have evolved so that the shape of their body allows them to live and flourish in their habitat, for example, primates with opposable thumbs. Unlike other animals primates are able to grasp and hold objects, which eventually led to our fine motor skills and development of tools.

Animal - Animal - Form and function: To stay alive, grow, and reproduce, an animal must find food, water, and oxygen, and it must eliminate the waste products of metabolism. The organ systems typical of all but the simplest of animals range from those highly specialized for one function to those participating in many. The more basic functional systems are treated below from a broadly ...

Animal tissues are grouped into four basic types: connective, muscle, nervous, and epithelial. Collections of tissues joined in units to serve a common function compose organs. While all animals can generally be considered to contain the four tissue types, the manifestation of these tissues can differ depending on the type of organism.

FOSSIL FORM AND FUNCTION. Summary: Paleontologists look at fossil pieces and compare them to living animals of today to determine what that fossil animal did (how it ate, what it ate, where it lived, how it defended itself). This activity gives students random fossil pieces and allows them to construct an animal and determine what it did.

Torpor is a process that leads to a decrease in activity and metabolism, which allows animals to survive adverse conditions. Torpor can be used by animals for long periods. For example, animals can enter a state of hibernation during the winter months, which enables them to maintain a reduced body temperature.

This suggests that plants and animals identified different solutions to the question of how a developmental program reliably generates multicellular form and function. The plant and animal lineages diverged before the evolution of multicellularity, and thus each kingdom represents an independent solution to the same basic problems in morphogenesis, built from the same unicellular toolkit.

Hence, their daily activities and functions vary, so do their cell structure. Cell structure and organelles vary in plants and animals, and they are primarily classified based on their function. The difference in their cell composition is the reason behind the difference between plants and animals, their structure and functions.
