Trophoblast giant cells (TGCs) are the first terminally differentiated subtype to form in the trophoblast cell lineage in rodents. In addition to mediating implantation, they are the main endocrine cells of the placenta, producing several hormones which regulate the maternal endocrine and immune systems and promote maternal blood flow to the implantation site.

SUBPOPULATIONS OF TROPHOBLAST. FUNCTIONAL ASPECTS. CT is the trophoblastic stem cell and is located on the villous surface. CT expresses epidermal growth factor receptor (EGF-R) which binds to EGF secreted by the decidua ().It has been postulated that paracrine-like mechanism EGF-R and its ligand may provide persistent growth stimulation for CT ().As discussed previously, CT differentiates ...

Defects in all the trophoblast-differentiating pathways--endovascular, interstitial and chorionic villous--play a role in the pathogenesis of early-onset intra-uterine growth restriction (IUGR). The cytotrophoblast (or layer of Langhans) is the inner layer of the trophoblast.It is interior to the syncytiotrophoblast and external to the wall of the blastocyst in a developing embryo.. The cytotrophoblast is considered to be the trophoblastic stem cell because the layer surrounding the blastocyst remains while daughter cells differentiate and proliferate to function in multiple roles.

Trophoblast invasion is a critical process in the establishment of a successful pregnancy. But abnormal trophoblast invasion is associated with pathological conditions such as IUGR, stillbirth, spontaneous abortion, and preeclampsia. Trophoblasts constitutively express two isoforms of NOS (eNOS and iNOS), which produce NO in cells.

The syncytiotrophoblast forms an external layer without intercellular boundaries (syncytium) and its cells form cords infiltrating the endometrium.The syncythiotrophoblast derives from the fusion of cytotrophoblast cells. Through apoptosis (programmed cell death) of uterine stromal cells spaces are created through which the blastocyst penetrates further into the endometrium.

Objective and rationale: This review explores the origins and possible uses of trophoblast cells obtained during ongoing pregnancies (weeks 5-20) by TRIC. We hypothesize that endoglandular EVT cells at the margins of the expanding placenta enter the uterine cavity and are carried together with uterine secretion products to the cervix where they can be retrieved from a Papanicolaou (Pap) smear.
